Five Colour Theorem: The vertices of a planar graph can be properly coloured with five colours.

We shall prove the result by induction on the number of vertices of graph  $G$ . If the number of vertices  $n$  in a graph is less than or equal to 5 then we can properly colour these vertices with five colours. Hence the result holds. We assume that the result holds for all planar graphs having less than  $n$  vertices. Now consider a planar graph with  $n$  vertices. Then it must have a vertex  $v$  with degree five or less. Let  $G' = G - v$ , the graph obtained from  $G$  by deleting vertex  $v$ . Then by induction hypothesis,  $G'$  (of  $n-1$  vertices) requires no more than five colours. Paint the vertices of  $G'$  with five colours and now add to it the vertex  $v$  along with all edges incident on  $v$ . If the degree of  $v$  is less than 4, we can assign a proper colour to  $v$  and obtain a proper colouring of  $G$ .

This leaves only a case when  $d(v) = 5$  and all the five colours have been used in colouring the vertices  $a, b, c, d$  and  $e$  adjacent to  $v$  as shown in Fig.

Let  $H$  be subgraph of  $G$  on the vertices which have been assigned the Colour 1 and Colour 3. Hence  $a, c$  are in  $H$ . If  $a$  and  $c$  belong to different components of  $H$ , then  $H$  can interchange the Colour 1 and 3 in the component

which contains vertex  $a$  without destroying the proper coloring of  $G-v$ . This interchange will paint vertices  $a$  and  $c$  with colour 2. Now colour 1 can be assigned to vertex  $v$  and thus  $G$  is  $k$ -chromatic. On the other hand, if  $a$  and  $c$  are in the same component of  $H$ . Then there is a path  $P$  from  $a$  to  $c$ . These vertices are painted alternately with colour 1 and 2 as shown in Fig. The path  $P$  together with the edges  $(a,v)$  and  $(c,v)$  form a circuit which encloses  $b$  as shown in Fig. Consider now the subgraph  $K$  of  $G$  on the vertices painted with colour 2 only. Since  $c$  encloses  $v$ , only  $b$  but not both, vertices  $b$  and  $d$  belong to different components of  $K$ . Therefore we can interchange the colours 2 and 4 in the component containing  $b$  without destroying the proper coloring of  $G-v$ . This interchange will paint vertices  $b$  and  $d$  with colour 4. Now colour 2 can be assigned to vertex  $v$ . Hence the theorem.
